

Package ‘hSDM’

December 3, 2013

Type Package

Title hierarchical Bayesian species distribution models

Version 1.2

Date 2013-10-15

Depends coda

Author Ghislain Vieilledent, Andrew M. Latimer, Alan E. Gelfand, Cory Merow, Adam M. Wilson, Frederic Mortier and John A. Silander Jr.

Maintainer Ghislain Vieilledent <ghislain.vieilledent@cirad.fr>

Description hSDM is an R package for estimating parameters of hierarchical Bayesian species distribution models. Such models allow interpreting the observations (occurrence and abundance of a species) as a result of several hierarchical processes including ecological processes (habitat suitability, spatial dependence and anthropogenic disturbance) and observation processes (species detectability). Hierarchical species distribution models are essential for accurately characterizing the environmental response of species, predicting their probability of occurrence, and assessing uncertainty in the model results.

hSDM.binomial

The hSDM.binomial function performs a Binomial logistic regression model in a Bayesian framework.

Description

The hSDM.binomial function calls a Gibbs sampler written in C code which uses a Metropolis algorithm to estimate the conditional posterior distribution of model's parameters.

Usage

```
hSDM.binomial(presences, trials, suitability, data, burnin =
5000, mcmc = 10000, thin = 10, beta.start, mubeta = 0, Vbeta = 1e+06,
seed = 1234, verbose = 1)
```

Arguments

presences	A vector indicating the number of successes (or presences) for each observation.
trials	A vector indicating the number of trials for each observation. t_n should be superior or equal to y_n , the number of successes for observation n . If $t_n = 0$, then $y_n = 0$.
suitability	A one-sided formula of the form '~x1+...+xp' with p terms specifying the explicative variables for the suitability process of the model.
data	A data frame containing the model's explicative variables.
burnin	The number of burnin iterations for the sampler.
mcmc	The number of Gibbs iterations for the sampler. Total number of Gibbs iterations is equal to burnin+mcmc. burnin+mcmc must be divisible by 10 and superior or equal to 100 so that the progress bar can be displayed.
thin	The thinning interval used in the simulation. The number of mcmc iterations must be divisible by this value.
beta.start	Starting values for beta parameters of the suitability process. If beta.start takes a scalar value, then that value will serve for all of the betas.
mubeta	Means of the priors for the β parameters of the suitability process. mubeta must be either a scalar or a p-length vector. If mubeta takes a scalar value, then that value will serve as the prior mean for all of the betas. The default value is set to 0 for an uninformative prior.
Vbeta	Variances of the Normal priors for the β parameters of the suitability process. Vbeta must be either a scalar or a p-length vector. If Vbeta takes a scalar value, then that value will serve as the prior variance for all of the betas. The default variance is large and set to 1.0E6 for an uninformative flat prior.
seed	The seed for the random number generator. Default to 1234.
verbose	A switch (0,1) which determines whether or not the progress of the sampler is printed to the screen. Default is 1: a progress bar is printed, indicating the step (in %) reached by the Gibbs sampler.

Value

mcmc	An mcmc object that contains the posterior sample. This object can be summarized by functions provided by the coda package. The posterior sample of the deviance D , with $D = -2 \log(\prod_i P(y_i, n_i \beta))$, is also provided.
------	--

prob.p.pred Predictive posterior mean of the probability associated to the suitability process for each spatial cell.

hSDM.binomial.iCAR

The hSDM.binomial.iCAR function performs a Binomial logistic regression model in a hierarchical Bayesian framework. The suitability process includes a spatial correlation process. The spatial correlation is modelled using an intrinsic CAR model.

Description

The `hSDM.binomial.iCAR` function calls a Gibbs sampler written in C code which uses a Metropolis algorithm to estimate the conditional posterior distribution of model's parameters.

Usage

```
hSDM.binomial.iCAR(presences, trials, suitability, cells,
n.neighbors, neighbors, data, burnin = 5000, mcmc = 10000, thin = 10,
beta.start, Vrho.start, mubeta = 0, Vbeta = 1e+06, priorVrho =
"1/Gamma", shape = 0.5, rate = 0.0005, Vrho.max = 1000, seed = 1234,
verbose = 1, save.rho = 0)
```

Arguments

<code>presences</code>	A vector indicating the number of successes (or presences) for each observation.
<code>trials</code>	A vector indicating the number of trials for each observation. t_n should be superior or equal to y_n , the number of successes for observation n . If $t_n = 0$, then $y_n = 0$.
<code>suitability</code>	A one-sided formula of the form ' $\sim x_1 + \dots + x_p$ ' with p terms specifying the explicative variables for the suitability process of the model.
<code>cells</code>	A vector indicating the spatial cell identifier (from 1 to total number of cell) for each observation. Several observations can occur in one spatial cell.
<code>n.neighbors</code>	A vector of integers indicating the number of neighbors (adjacent cells) of each spatial cell.
<code>neighbors</code>	A vector of integers indicating the neighbors (adjacent cells) of each spatial cell. Must be of the form $c(\text{neighbors of cell 1, neighbors of cell 2, } \dots, \text{neighbors of the last cell})$. Length of the <code>neighbors</code> vector should be equal to <code>sum(data\$num)</code> .
<code>data</code>	A data frame containing the model's explicative variables.
<code>burnin</code>	The number of burnin iterations for the sampler.
<code>mcmc</code>	The number of Gibbs iterations for the sampler. Total number of Gibbs iterations is equal to <code>burnin+mcmc</code> . <code>burnin+mcmc</code> must be divisible by 10 and superior or equal to 100 so that the progress bar can be displayed.
<code>thin</code>	The thinning interval used in the simulation. The number of <code>mcmc</code> iterations must be divisible by this value.
<code>beta.start</code>	Starting values for beta parameters.
<code>Vrho.start</code>	Positive scalar indicating the starting value for the variance of the spatial random effects.
<code>mubeta</code>	Means of the priors for the β parameters of the suitability process. <code>mubeta</code> must be either a scalar or a p -length vector. If <code>mubeta</code> takes a scalar value, then that value will serve as the prior mean for all of the betas. The default value is set to 0 for an uninformative prior.
<code>Vbeta</code>	Variances of the Normal priors for the β parameters of the suitability process. <code>Vbeta</code> must be either a scalar or a p -length vector. If <code>Vbeta</code> takes a scalar value, then that value will serve as the prior variance for all of the betas. The default variance is large and set to $1.0E6$ for an uninformative flat prior.

priorVrho	Type of prior for the variance of the spatial random effects. Can be set to a fixed positive scalar, or to an inverse-gamma distribution ("1/Gamma") with parameters shape and rate, or to a uniform distribution ("Uniform") on the interval [0,Vrho.max]. Default to "1/Gamma".
shape	The shape parameter for the Gamma prior on the precision of the spatial random effects. Default value is shape=0.05 for uninformative prior.
rate	The rate (1/scale) parameter for the Gamma prior on the precision of the spatial random effects. Default value is rate=0.0005 for uninformative prior.
Vrho.max	Upper bound for the uniform prior of the spatial random effect variance. Default to 1000.
seed	The seed for the random number generator. Default to 1234.
verbose	A switch (0,1) which determines whether or not the progress of the sampler is printed to the screen. Default is 1: a progress bar is printed, indicating the step (in %) reached by the Gibbs sampler.
save.rho	A switch (0,1) which determines whether or not the sampled values for rhos are saved. Default is 0: the posterior mean is computed and returned in the rho.pred vector. Be careful, setting save.rho to 1 might require a large amount of memory.

Value

mcmc	An mcmc object that contains the posterior sample. This object can be summarized by functions provided by the coda package. The posterior sample of the deviance D , with $D = -2 \log(\prod_i P(y_i, n_i \beta, \rho_i))$, is also provided.
rho.pred	If save.rho is set to 0 (default), rho.pred is the predictive posterior mean of the spatial random effect associated to each spatial cell. If save.rho is set to 1, rho.pred is an mcmc object with sampled values for each spatial random effect associated to each spatial cell.
prob.p.pred	Predictive posterior mean of the probability associated to the suitability process for each spatial cell.

hSDM.hierarchical.binomial

The hSDM.hierarchical.binomial function can be used to model species distribution including different processes in a hierarchical Bayesian framework: (i) a Bernoulli suitability process (referring to environmental suitability) which takes into account the spatial dependence of the observations, (ii) an alteration process (referring to anthropogenic disturbances), and (iii) a Binomial observability process (referring to various ecological and methodological issues explaining the species presence). The model reduces to a ZIB (Zero-Inflated Binomial) model with spatial dependence if the alteration is set to zero.

Description

The hSDM.hierarchical.binomial function calls a Gibbs sampler written in C code which uses a Metropolis algorithm to estimate the conditional posterior distribution of hierarchical model's parameters.

Usage

```

hSDM.hierarchical.binomial(presences, trials, suitability, cells,
n.neighbors, neighbors, alteration, observability, data, burnin = 5000,
mcmc = 10000, thin = 10, beta.start, gamma.start, Vrho.start, mubeta =
0, Vbeta = 1e+06, mugamma = 0, Vgamma = 1e+06, priorVrho = "1/Gamma",
shape = 0.5, rate = 0.0005, Vrho.max=1000, seed = 1234, verbose = 1,
save.rho = 0)

```

Arguments

presences	A vector indicating the number of successes (or presences) for each observation.
trials	A vector indicating the number of trials for each observation. t_n should be superior or equal to y_n , the number of successes for observation n . If $t_n = 0$, then $y_n = 0$.
suitability	A one-sided formula of the form '~x1+...+xp' with p terms specifying the explicative variables for the suitability process of the model.
cells	A vector indicating the spatial cell identifier (from 1 to total number of cell) for each observation. Several observations can occur in one spatial cell.

n.neighbors	A vector of integers that indicates the number of neighbors (adjacent cells) of each spatial cell.
neighbors	A vector of integers indicating the neighbors (adjacent cells) of each spatial cell. Must be of the form c(neighbors of cell 1, neighbors of cell 2, ... , neighbors of the last cell). Length of the neighbors vector should be equal to sum(data\$num).
alteration	A vector indicating the proportion of area in the spatial cell which is transformed (by anthropogenic activities for example) for each observation. Must be between 0 and 1.
observability	A one-sided formula of the form ' $\sim x_1 + \dots + x_q$ ' with q terms specifying the explicative variables for the observability process of the model.
data	A data frame containing the model's variables.
burnin	The number of burnin iterations for the sampler.
mcmc	The number of Gibbs iterations for the sampler. Total number of Gibbs iterations is equal to burnin+mcmc. burnin+mcmc must be divisible by 10 and superior or equal to 100 so that the progress bar can be displayed.
thin	The thinning interval used in the simulation. The number of mcmc iterations must be divisible by this value.
beta.start	Starting values for beta parameters.
gamma.start	Starting values for gamma parameters.
Vrho.start	Positive scalar indicating the starting value for the variance of the spatial random effects.
mubeta	Means of the priors for the β parameters of the suitability process. mubeta must be either a scalar or a p-length vector. If mubeta takes a scalar value, then that value will serve as the prior mean for all of the betas. The default value is set to 0 for an uninformative prior.
Vbeta	Variances of the Normal priors for the β parameters of the suitability process. Vbeta must be either a scalar or a p-length vector. If Vbeta takes a scalar value, then that value will serve as the prior variance for all of the betas. The default variance is large and set to 1.0E6 for an uninformative flat prior.
mugamma	Means of the Normal priors for the γ parameters of the observability process. mugamma must be either a scalar or a p-length vector. If mugamma takes a scalar value, then that value will serve as the prior mean for all of the gammas. The default value is set to 0 for an uninformative prior.
Vgamma	Variances of the Normal priors for the γ parameters of the observability process. Vgamma must be either a scalar or a p-length vector. If Vgamma takes a scalar value, then that value will serve as the prior variance for all of the gammas. The default variance is large and set to 1.0E6 for an uninformative flat prior.
priorVrho	Type of prior for the variance of the spatial random effects. Can be set to a fixed positive scalar, or to an inverse-gamma distribution ("1/Gamma") with parameters shape and rate, or to a uniform distribution ("Uniform") on the interval [0,Vrho.max]. Default to "1/Gamma".
shape	The shape parameter for the Gamma prior on the precision of the spatial random effects. Default value is shape=0.05 for uninformative prior.

rate	The rate (1/scale) parameter for the Gamma prior on the precision of the spatial random effects. Default value is rate=0.0005 for uninformative prior.
Vrho.max	Upper bound for the uniform prior of the spatial random effect variance. Default to 1000.
seed	The seed for the random number generator. Default to 1234.
verbose	A switch (0,1) which determines whether or not the progress of the sampler is printed to the screen. Default is 1: a progress bar is printed, indicating the step (in %) reached by the Gibbs sampler.
save.rho	A switch (0,1) which determines whether or not the sampled values for rhos are saved. Default is 0: the posterior mean is computed and returned in the rho.pred vector. Be careful, setting save.rho to 1 might require a large amount of memory.

Value

mcmc	An mcmc object that contains the posterior sample. This object can be summarized by functions provided by the coda package. The posterior sample of the deviance D , with $D = -2 \log(\prod_i P(y_i, n_i u_i, \beta, \gamma, \rho_i))$, is also provided.
rho.pred	If save.rho is set to 0 (default), rho.pred is the predictive posterior mean of the spatial random effect associated to each spatial cell. If save.rho is set to 1, rho.pred is an mcmc object with sampled values for each spatial random effect associated to each spatial cell.
prob.p.pred	Predictive posterior mean of the probability associated to the suitability process for each spatial cell.
prob.q.pred	Predictive posterior mean of the probability associated to the observability process for each spatial cell.

hSDM.hierarchical.poisson

The hSDM.hierarchical.poisson function can be used to model species distribution including different processes in a hierarchical Bayesian framework: (i) a Bernoulli suitability process (referring to environmental suitability) which takes into account the spatial dependence of the observations, (ii) an alteration process (referring to anthropogenic disturbances), and (iii) a Poisson observability process (referring to various ecological and methodological issues explaining the species abundance). The model reduces to a ZIP (Zero-Inflated Poisson) model with spatial dependence if the alteration is set to zero.

Description

The hSDM.hierarchical.poisson function calls a Gibbs sampler written in C code which uses a Metropolis algorithm to estimate the conditional posterior distribution of model's parameters.

Usage

```

hSDM.hierarchical.poisson(counts, visits, suitability, cells,
n.neighbors, neighbors, alteration, observability, data, burnin = 5000,
mcmc = 10000, thin = 10, beta.start, gamma.start, Vrho.start, mubeta =
0, Vbeta = 1e+06, mugamma = 0, Vgamma = 1e+06, priorVrho = "1/Gamma",
shape = 0.5, rate = 0.0005, Vrho.max=1000, seed = 1234, verbose = 1,
save.rho = 0)

```

Arguments

counts A vector indicating the count (or abundance) for each observation.

<code>visits</code>	A vector indicating if the observation point n has been visited (<code>visits[n]=1</code>) or not (<code>visits[n]=0</code>). If <code>visits[n]=0</code> , then <code>counts[n]=0</code> .
<code>suitability</code>	A one-sided formula of the form ' $\sim x_1 + \dots + x_p$ ' with p terms specifying the explicative variables for the suitability process of the model.
<code>cells</code>	A vector indicating the spatial cell identifier (from 1 to total number of cell) for each observation. Several observations can occur in one spatial cell.
<code>n.neighbors</code>	A vector of integers that indicates the number of neighbors (adjacent cells) of each spatial cell.
<code>neighbors</code>	A vector of integers indicating the neighbors (adjacent cells) of each spatial cell. Must be of the form <code>c(neighbors of cell 1, neighbors of cell 2, ... , neighbors of the last cell)</code> . Length of the <code>neighbors</code> vector should be equal to <code>sum(data\$num)</code> .
<code>alteration</code>	A vector indicating the proportion of area in the spatial cell which is transformed (by anthropogenic activities for example) for each observation. Must be between 0 and 1.
<code>observability</code>	A one-sided formula of the form ' $\sim x_1 + \dots + x_q$ ' with q terms specifying the explicative variables for the observability process of the model.
<code>data</code>	A data frame containing the model's explicative variables.
<code>burnin</code>	The number of burnin iterations for the sampler.
<code>mcmc</code>	The number of Gibbs iterations for the sampler. Total number of Gibbs iterations is equal to <code>burnin+mcmc</code> . <code>burnin+mcmc</code> must be divisible by 10 and superior or equal to 100 so that the progress bar can be displayed.
<code>thin</code>	The thinning interval used in the simulation. The number of mcmc iterations must be divisible by this value.
<code>beta.start</code>	Starting values for beta parameters.
<code>gamma.start</code>	Starting values for gamma parameters.
<code>Vrho.start</code>	Positive scalar indicating the starting value for the variance of the spatial random effects.
<code>mubeta</code>	Means of the priors for the β parameters of the suitability process. <code>mubeta</code> must be either a scalar or a p -length vector. If <code>mubeta</code> takes a scalar value, then that value will serve as the prior mean for all of the betas. The default value is set to 0 for an uninformative prior.
<code>Vbeta</code>	Variances of the Normal priors for the β parameters of the suitability process. <code>Vbeta</code> must be either a scalar or a p -length vector. If <code>Vbeta</code> takes a scalar value, then that value will serve as the prior variance for all of the betas. The default variance is large and set to $1.0E6$ for an uninformative flat prior.
<code>mugamma</code>	Means of the Normal priors for the γ parameters of the observability process. <code>mugamma</code> must be either a scalar or a p -length vector. If <code>mugamma</code> takes a scalar value, then that value will serve as the prior mean for all of the gammas. The default value is set to 0 for an uninformative prior.
<code>Vgamma</code>	Variances of the Normal priors for the γ parameters of the observability process. <code>Vgamma</code> must be either a scalar or a p -length vector. If <code>Vgamma</code> takes a scalar value, then that value will serve as the prior variance for all of the gammas. The default variance is large and set to $1.0E6$ for an uninformative flat prior.

priorVrho	Type of prior for the variance of the spatial random effects. Can be set to a fixed positive scalar, or to an inverse-gamma distribution ("1/Gamma") with parameters shape and rate, or to a uniform distribution ("Uniform") on the interval [0,Vrho.max]. Default to "1/Gamma".
shape	The shape parameter for the Gamma prior on the precision of the spatial random effects. Default value is shape=0.05 for uninformative prior.
rate	The rate (1/scale) parameter for the Gamma prior on the precision of the spatial random effects. Default value is rate=0.0005 for uninformative prior.
Vrho.max	Upper bound for the uniform prior of the spatial random effect variance. Default to 1000.
seed	The seed for the random number generator. Default to 1234.
verbose	A switch (0,1) which determines whether or not the progress of the sampler is printed to the screen. Default is 1: a progress bar is printed, indicating the step (in %) reached by the Gibbs sampler.
save.rho	A switch (0,1) which determines whether or not the sampled values for rhos are saved. Default is 0: the posterior mean is computed and returned in the rho.pred vector. Be careful, setting save.rho to 1 might require a large amount of memory.

Value

mcmc	An mcmc object that contains the posterior sample. This object can be summarized by functions provided by the coda package. The posterior sample of the deviance D , with $D = -2 \log(\prod_i P(y_i, n_i u_i, \beta, \gamma, \rho_i))$, is also provided.
rho.pred	If save.rho is set to 0 (default), rho.pred is the predictive posterior mean of the spatial random effect associated to each spatial cell. If save.rho is set to 1, rho.pred is an mcmc object with sampled values for each spatial random effect associated to each spatial cell.
prob.p.pred	Predictive posterior mean of the probability associated to the suitability process for each spatial cell.
prob.q.pred	Predictive posterior mean of the probability associated to the observability process for each spatial cell.

hSDM.poisson

The hSDM.poisson function performs a Poisson regression in a Bayesian framework.

Description

The hSDM.poisson function calls a Gibbs sampler written in C code which uses a Metropolis algorithm to estimate the conditional posterior distribution of model's parameters.

Usage

```
hSDM.poisson(counts, visits, suitability, data, burnin = 5000, mcmc =
10000, thin = 10, beta.start, mubeta = 0, Vbeta = 1e+06, seed = 1234,
verbose = 1)
```

Arguments

counts	A vector indicating the count (or abundance) for each observation.
visits	A vector indicating if the observation point n has been visited (visits[n]=1) or not (visits[n]=0). If visits[n]=0, then counts[n]=0.
suitability	A one-sided formula of the form '~x1+...+xp' with p terms specifying the explicative covariates for the suitability process of the model.
data	A data frame containing the model's explicative variables.
burnin	The number of burnin iterations for the sampler.

mcmc	The number of Gibbs iterations for the sampler. Total number of Gibbs iterations is equal to burnin+mcmc. burnin+mcmc must be divisible by 10 and superior or equal to 100 so that the progress bar can be displayed.
thin	The thinning interval used in the simulation. The number of mcmc iterations must be divisible by this value.
beta.start	Starting values for beta parameters of the suitability process. If beta.start takes a scalar value, then that value will serve for all of the betas.
mubeta	Means of the priors for the β parameters of the suitability process. mubeta must be either a scalar or a p-length vector. If mubeta takes a scalar value, then that value will serve as the prior mean for all of the betas. The default value is set to 0 for an uninformative prior.
Vbeta	Variances of the Normal priors for the β parameters of the suitability process. Vbeta must be either a scalar or a p-length vector. If Vbeta takes a scalar value, then that value will serve as the prior variance for all of the betas. The default variance is large and set to 1.0E6 for an uninformative flat prior.
seed	The seed for the random number generator. Default to 1234.
verbose	A switch (0,1) which determines whether or not the progress of the sampler is printed to the screen. Default is 1: a progress bar is printed, indicating the step (in %) reached by the Gibbs sampler.

Value

mcmc	An mcmc object that contains the posterior sample. This object can be summarized by functions provided by the coda package. The posterior sample of the deviance D , with $D = -2 \log(\prod_i P(y_i, n_i \beta))$, is also provided.
prob.p.pred	Predictive posterior mean of the probability associated to the suitability process for each spatial cell.

hSDM.poisson.iCAR	<i>The hSDM.poisson.iCAR function performs a Poisson regression in a hierarchical Bayesian framework. The suitability process includes a spatial correlation process. The spatial correlation is modelled using an intrinsic CAR model.</i>
-------------------	---

Description

The hSDM.poisson.iCAR function calls a Gibbs sampler written in C code which uses a Metropolis algorithm to estimate the conditional posterior distribution of model's parameters.

Usage

```

hSDM.poisson.iCAR(counts, visits, suitability, cells,
n.neighbors, neighbors, data, burnin = 5000, mcmc = 10000, thin = 10,
beta.start, Vrho.start, mubeta = 0, Vbeta = 1e+06, priorVrho =
"1/Gamma", shape = 0.5, rate = 0.0005, Vrho.max = 1000, seed = 1234,
verbose = 1, save.rho = 0)

```

Arguments

counts	A vector indicating the count (or abundance) for each observation.
visits	A vector indicating if the observation point n has been visited (visits[n]=1) or not (visits[n]=0). If visits[n]=0, then counts[n]=0.

suitability	A one-sided formula of the form ' $\sim x_1 + \dots + x_p$ ' with p terms specifying the explicative variables for the suitability process of the model.
cells	A vector indicating the spatial cell identifier (from 1 to total number of cell) for each observation. Several observations can occur in one spatial cell.
n.neighbors	A vector of integers that indicates the number of neighbors (adjacent cells) of each spatial cell.
neighbors	A vector of integers indicating the neighbors (adjacent cells) of each spatial cell. Must be of the form $c(\text{neighbors of cell 1, neighbors of cell 2, } \dots, \text{neighbors of the last cell})$. Length of the neighbors vector should be equal to $\text{sum}(\text{data}\$num)$.
data	A data frame containing the model's explicative variables.
burnin	The number of burnin iterations for the sampler.
mcmc	The number of Gibbs iterations for the sampler. Total number of Gibbs iterations is equal to $\text{burnin} + \text{mcmc}$. $\text{burnin} + \text{mcmc}$ must be divisible by 10 and superior or equal to 100 so that the progress bar can be displayed.
thin	The thinning interval used in the simulation. The number of mcmc iterations must be divisible by this value.
beta.start	Starting values for beta parameters.
Vrho.start	Positive scalar indicating the starting value for the variance of the spatial random effects.
mubeta	Means of the priors for the β parameters of the suitability process. mubeta must be either a scalar or a p -length vector. If mubeta takes a scalar value, then that value will serve as the prior mean for all of the betas. The default value is set to 0 for an uninformative prior.
Vbeta	Variances of the Normal priors for the β parameters of the suitability process. Vbeta must be either a scalar or a p -length vector. If Vbeta takes a scalar value, then that value will serve as the prior variance for all of the betas. The default variance is large and set to $1.0E6$ for an uninformative flat prior.
priorVrho	Type of prior for the variance of the spatial random effects. Can be set to a fixed positive scalar, or to an inverse-gamma distribution (" $1/\text{Gamma}$ ") with parameters shape and rate, or to a uniform distribution ("Uniform") on the interval $[0, Vrho.max]$. Default to " $1/\text{Gamma}$ ".
shape	The shape parameter for the Gamma prior on the precision of the spatial random effects. Default value is $\text{shape} = 0.05$ for uninformative prior.
rate	The rate ($1/\text{scale}$) parameter for the Gamma prior on the precision of the spatial random effects. Default value is $\text{rate} = 0.0005$ for uninformative prior.
Vrho.max	Upper bound for the uniform prior of the spatial random effect variance. Default to 1000.
seed	The seed for the random number generator. Default to 1234.
verbose	A switch (0,1) which determines whether or not the progress of the sampler is printed to the screen. Default is 1: a progress bar is printed, indicating the step (in %) reached by the Gibbs sampler.

`save.rho` A switch (0,1) which determines whether or not the sampled values for rhos are saved. Default is 0: the posterior mean is computed and returned in the `rho.pred` vector. Be careful, setting `save.rho` to 1 might require a large amount of memory.

Value

`mcmc` An mcmc object that contains the posterior sample. This object can be summarized by functions provided by the coda package. The posterior sample of the deviance D , with $D = -2 \log(\prod_i P(y_i, n_i | \beta, \rho_i))$, is also provided.

`rho.pred` If `save.rho` is set to 0 (default), `rho.pred` is the predictive posterior mean of the spatial random effect associated to each spatial cell. If `save.rho` is set to 1, `rho.pred` is an mcmc object with sampled values for each spatial random effect associated to each spatial cell.

`prob.p.pred` Predictive posterior mean of the probability associated to the suitability process for each spatial cell.

hSDM.site.occupancy *The hSDM.site.occupancy function can be used to model species distribution including different processes in a hierarchical Bayesian framework: a Bernoulli suitability process (referring to environmental suitability) which takes into account the spatial dependence of the observations, and a Binomial observability process (referring to various ecological and methodological issues explaining the species detection).*

Description

The hSDM.site.occupancy function calls a Gibbs sampler written in C code which uses a Metropolis algorithm to estimate the conditional posterior distribution of hierarchical model's parameters.

Usage

```
hSDM.site.occupancy(presences, trials, suitability,
observability, spatial.entity, data, n.neighbors, neighbors,
suitability.pred=NULL, spatial.entity.pred=NULL, burnin = 5000, mcmc =
10000, thin = 10, beta.start, gamma.start, Vrho.start, mubeta = 0, Vbeta
= 1e+06, mugamma = 0, Vgamma = 1e+06, priorVrho = "1/Gamma", shape =
0.5, rate = 0.0005, Vrho.max=1000, seed = 1234, verbose = 1, save.rho =
0, save.p = 0)
```

Arguments

presences	A vector indicating the number of successes (or presences) for each observation.
trials	A vector indicating the number of trials for each observation. t_i should be superior to zero and superior or equal to y_i , the number of successes for observation i .
suitability	A one-sided formula of the form $\sim x_1 + \dots + x_p$ with p terms specifying the explicative variables for the suitability process.
observability	A one-sided formula of the form $\sim w_1 + \dots + w_q$ with q terms specifying the explicative variables for the observability process.
spatial.entity	A vector indicating the spatial entity identifier (from one to the total number of entities) for each observation. Several observations can occur in one spatial entity. A spatial entity can be a raster cell for example.
data	A data frame containing the model's variables.
n.neighbors	A vector of integers that indicates the number of neighbors (adjacent entities) of each spatial entity. length(n.neighbors) indicates the total number of spatial entities.
neighbors	A vector of integers indicating the neighbors (adjacent entities) of each spatial entity. Must be of the form c(neighbors of entity 1, neighbors of entity 2, ... , neighbors of the last entity). Length of the neighbors vector should be equal to sum(n.neighbors).

suitability.pred	An optional data frame in which to look for variables with which to predict. If NULL, the observations are used.
spatial.entity.pred	An optional vector indicating the spatial entity identifier (from one to the total number of entities) for predictions. If NULL, the vector spatial.entity for observations is used.
burnin	The number of burnin iterations for the sampler.
mcmc	The number of Gibbs iterations for the sampler. Total number of Gibbs iterations is equal to burnin+mcmc. burnin+mcmc must be divisible by 10 and superior or equal to 100 so that the progress bar can be displayed.
thin	The thinning interval used in the simulation. The number of mcmc iterations must be divisible by this value.
beta.start	Starting values for β parameters of the suitability process. This can either be a scalar or a p -length vector.
gamma.start	Starting values for β parameters of the observability process. This can either be a scalar or a q -length vector.
Vrho.start	Positive scalar indicating the starting value for the variance of the spatial random effects.
mubeta	Means of the priors for the β parameters of the suitability process. mubeta must be either a scalar or a p -length vector. If mubeta takes a scalar value, then that value will serve as the prior mean for all of the betas. The default value is set to 0 for an uninformative prior.
Vbeta	Variances of the Normal priors for the β parameters of the suitability process. Vbeta must be either a scalar or a p -length vector. If Vbeta takes a scalar value, then that value will serve as the prior variance for all of the betas. The default variance is large and set to 1.0E6 for an uninformative flat prior.
mugamma	Means of the Normal priors for the γ parameters of the observability process. mugamma must be either a scalar or a p -length vector. If mugamma takes a scalar value, then that value will serve as the prior mean for all of the gammas. The default value is set to 0 for an uninformative prior.
Vgamma	Variances of the Normal priors for the γ parameters of the observability process. Vgamma must be either a scalar or a p -length vector. If Vgamma takes a scalar value, then that value will serve as the prior variance for all of the gammas. The default variance is large and set to 1.0E6 for an uninformative flat prior.
priorVrho	Type of prior for the variance of the spatial random effects. Can be set to a fixed positive scalar, or to an inverse-gamma distribution ("1/Gamma") with parameters shape and rate, or to a uniform distribution ("Uniform") on the interval [0,Vrho.max]. Default set to "1/Gamma".
shape	The shape parameter for the Gamma prior on the precision of the spatial random effects. Default value is shape=0.05 for uninformative prior.
rate	The rate (1/scale) parameter for the Gamma prior on the precision of the spatial random effects. Default value is rate=0.0005 for uninformative prior.
Vrho.max	Upper bound for the uniform prior of the spatial random effect variance. Default set to 1000.

seed	The seed for the random number generator. Default set to 1234.
verbose	A switch (0,1) which determines whether or not the progress of the sampler is printed to the screen. Default is 1: a progress bar is printed, indicating the step (in %) reached by the Gibbs sampler.
save.rho	A switch (0,1) which determines whether or not the sampled values for rhos are saved. Default is 0: the posterior mean is computed and returned in the rho.pred vector. Be careful, setting save.rho to 1 might require a large amount of memory.
save.p	A switch (0,1) which determines whether or not the sampled values for predictions are saved. Default is 0: the posterior mean is computed and returned in the prob.p.pred vector. Be careful, setting save.p to 1 might require a large amount of memory.

Details

The model integrates two processes, an ecological process associated to the presence or absence of the species due to habitat suitability and an observation process that takes into account the fact that the probability of detection of the species is inferior to one. The ecological process includes an intrinsic conditional autoregressive model (iCAR) model for spatial autocorrelation between observations, assuming that the probability of presence of the species at one site depends on the probability of presence of the species on neighboring sites.

Ecological process:

$$z_i \sim \text{Bernoulli}(\theta_i)$$

$$\text{logit}(\theta_i) = X_i\beta + \rho_{j(i)}$$

ρ_j : spatial random effect

$j(i)$: index of the spatial entity for observation i .

Spatial autocorrelation:

An intrinsic conditional autoregressive model (iCAR) is assumed:

$$\rho_j \sim \text{Normal}(\mu_j, V_\rho/n_j)$$

μ_j : mean of $\rho_{j'}$ in the neighborhood of j .

V_ρ : variance of the spatial random effects.

n_j : number of neighbors for spatial entity j .

Observation process:

$$y_i \sim \text{Binomial}(z_i * \delta_i, t_i)$$

$$\text{logit}(\delta_i) = W_i\gamma$$

Value

mcmc	An mcmc object that contains the posterior sample. This object can be summarized by functions provided by the coda package. The posterior sample of the deviance D , with $D = -2 \log(\prod_i P(y_i, n_i u_i, \beta, \gamma, \rho_i))$, is also provided.
------	---

rho.pred	If save.rho is set to 0 (default), rho.pred is the predictive posterior mean of the spatial random effect associated to each spatial entity. If save.rho is set to 1, rho.pred is an mcmc object with sampled values for each spatial random effect associated to each spatial entity.
prob.p.pred	If save.p is set to 0 (default), prob.p.pred is the predictive posterior mean of the probability associated to the suitability process for each prediction. If save.p is set to 1, prob.p.pred is an mcmc object with sampled values of the probability associated to the suitability process for each prediction.
prob.p.latent	Predictive posterior mean of the probability associated to the suitability process for each observation.
prob.q.latent	Predictive posterior mean of the probability associated to the observability process for each observation.

logit

*Generalized logit and inverse logit function***Description**

Compute generalized logit and generalized inverse logit functions.

Usage

```

logit(x, min = 0, max = 1)
inv.logit(x, min = 0, max = 1)

```

Arguments

x	value(s) to be transformed
min	Lower end of logit interval
max	Upper end of logit interval

Details

The generalized logit function takes values on [min, max] and transforms them to span [-Inf,Inf] it is defined as:

$$y = \log\left(\frac{p}{(1-p)}\right)$$

where

$$p = \frac{(x - \min)}{(\max - \min)}$$

The generalized inverse logit function provides the inverse transformation:

$$x = p'(max - min) + min$$

where

$$p' = \frac{\exp(y)}{(1 + \exp(y))}$$

Value

Transformed value(s).

Author(s)

Gregory R. Warnes <greg@warnes.net>

hSDM.binomial, [2](#)
hSDM.binomial.iCAR, [5](#)
hSDM.hierarchical.binomial, [10](#)
hSDM.hierarchical.poisson, [15](#)
hSDM.poisson, [20](#)
hSDM.poisson.iCAR, [23](#)
hSDM.site.occupancy, [28](#)

*Topic **Metropolis algorithm**

hSDM-package, [2](#)
hSDM.binomial, [2](#)
hSDM.binomial.iCAR, [5](#)
hSDM.hierarchical.binomial, [10](#)
hSDM.hierarchical.poisson, [15](#)
hSDM.poisson, [20](#)
hSDM.poisson.iCAR, [23](#)
hSDM.site.occupancy, [28](#)

*Topic **Poisson regression**

hSDM.poisson, [20](#)
hSDM.poisson.iCAR, [23](#)

*Topic **ZIB models**

hSDM.hierarchical.binomial, [10](#)
hSDM.site.occupancy, [28](#)

*Topic **ZIP models**

hSDM.hierarchical.poisson, [15](#)

*Topic **biodiversity**

hSDM-package, [2](#)

hSDM.binomial, [2](#)

hSDM.binomial.iCAR, [5](#)

hSDM.hierarchical.binomial, [10](#)

hSDM.hierarchical.poisson, [15](#)

hSDM.poisson, [20](#)

hSDM.poisson.iCAR, [23](#)

hSDM.site.occupancy, [28](#)

*Topic **conditional autoregressive model**

hSDM-package, [2](#)

hSDM.binomial.iCAR, [5](#)

hSDM.hierarchical.binomial, [10](#)

hSDM.hierarchical.poisson, [15](#)

hSDM.poisson.iCAR, [23](#)

hSDM.site.occupancy, [28](#)

*Topic **hierarchical Bayesian models**

hSDM-package, [2](#)

hSDM.binomial.iCAR, [5](#)

hSDM.hierarchical.binomial, [10](#)

hSDM.hierarchical.poisson, [15](#)

hSDM.poisson.iCAR, [23](#)

hSDM.site.occupancy, [28](#)

*Topic **intrinsic CAR model**

hSDM-package, [2](#)

hSDM.binomial.iCAR, [5](#)

hSDM.hierarchical.binomial, [10](#)

hSDM.hierarchical.poisson, [15](#)

hSDM.poisson.iCAR, [23](#)

hSDM.site.occupancy, [28](#)

*Topic **math**

logit, [35](#)

*Topic **spatial correlation**

hSDM-package, [2](#)

hSDM.binomial.iCAR, [5](#)

hSDM.hierarchical.binomial, [10](#)

hSDM.hierarchical.poisson, [15](#)

hSDM.poisson.iCAR, [23](#)

hSDM.site.occupancy, [28](#)

***Topic species distribution models**
